Abstract
Bronchial asthma (BA) is a serious problem affecting the quality of life of patients. Long non-coding RNAs (lncRNAs) are involved in BA. This study set out to investigate expressions of PVT1/miR-423-5p in the serum of BA patients and its clinical value on BA diagnosis and evaluation. This study included the same number (N = 100) of patients with BA at remission (BA-R), BA at exacerbation (BA-E), and healthy controls. PVT1 level was increased in BA-R and BA-E patients, and PVT1 level was higher in BA-E patients than BA-R patients. miR-141-3p targeted PVT1. miR-423-5p was downregulated in the serum of BA patients and was negatively correlated with PVT1. Area under ROC curve of PVT1/miR-423-5p axis on BA-R patients was 0.837 with sensitivity 0.74, specificity 0.84, while that of BA-E was 0.974 with sensitivity 0.87 and specificity 0.95. PVT1/miR-423-5p axis was negatively correlated with FEV1/FVC, FEV1% pred, and IL-10, and positively correlated with IgE, TNF-α, and IL-6. PVT1 and PVT1/miR-423-5p axis were associated with increased severity while miR-423-5p axis was negatively associated with BA severity. In conclusion, increased levels of PVT1/miR-423-5p had higher diagnostic efficiency on BA patients, especially patients with acute exacerbation.

Introduction

Bronchial asthma (BA) is a prevalent chronic disease of the airway which involves many cells and cellular components. Asthma is a complex syndrome with a variety of pathophysiological mechanisms. Recent data showed that BA has affected more than 10% of the population and the prevalence continues to increase. BA at remission (BA-R) is the absence of asthma symptoms for a period of time, while BA at exacerbation (BA-E) is a progressive increase in asthma symptoms. In recent years, the incidence and mortality rate of BA is on the rise due to the deterioration of environmental pollution, which adversely impacts the health condition and the quality of life of BA patients. Therefore, seeking novel biomarkers for BA diagnosis and treatment is critical for BA patients.

Long noncoding RNAs (lncRNAs) are a heterogeneous group of noncoding RNAs with a length of 200-100,000 nt. LncRNAs regulate protein expression or transcriptional and post-transcriptional level, and participate in the development of multiple diseases including asthma through many mechanisms. Based on the existing study, lncRNA plasmacytoma variant translocation 1 (PVT1) might be important in asthma and lncRNA PVT1 exacerbates inflammation and cell-barrier injury during asthma by modulating miR-149. According to the study of Austin et al., PTV1 was upregulated in the primary airway smooth muscle cells of patients with asthma and PVT1 expression might affect the proliferation of airway smooth muscle cells and the release of interleukin (IL)-6. However, the expression of lncRNA PVT1 in the serum of BA patients and whether lncRNA PTV1 could be used for BA diagnosis and treatment require further investigation.

The biological function of lncRNA PTV1 needs to be clarified. Accumulating evidence has reported the effect of lncRNA/microRNAs (miRNAs) in BA, indicating its association with the etiology of BA. The downstream miRNAs of lncRNA PVT1 were obtained through bioinformatics analysis. miR-423-5p, as one of the downstream miRNAs, was downregulated in the Th2-pretreated human airway epithelial cells, which suggested that miR-423-5p might be critical in changing the pro-inflammatory and anti-viral responses in BA-E patients. But, the expression of miR-423-5p in the serum of BA patients, and the association of the lncRNA PVT1/miR-423-5p axis with the risk, severity, and inflammatory cytokines of BA has not been reported at home and abroad. This study intended to study the expressions of lncRNA PVT1/miR-423-5p and explore the clinical values of the lncRNA PVT1/miR-423-5p axis on BA diagnosis and severity evaluation.

Material and Methods

Ethics statement

This study was authorized by the Ethics Committee of Zibo hospital for the prevention and treatment of occupational diseases. All participants signed the informed consent before being recruited for the study.

Participants

In this study, 100 patients with BA-E and 100 patients with BA-R were recruited in Zibo hospital for the prevention and treatment of occupational diseases between June 2019 and June 2020. The diagnosis accorded with the Global Initiative for Asthma (GINA) guidelines (2016). The inclusion criteria for BA-E patients were: (1) diagnosed as BA according to the guideline; (2) manifested with exacerbated symptoms including dyspnea, chest tightness, and serious cough; and (3) aged above 18 years. The inclusion criteria for BA-R patients were: (1) diagnosed as BA according to the guideline; (2) with clinical remission status, the symptoms disappeared and pulmonary function was improved to the pre-acute level and maintained at least for 3 months; and (3) aged above 18 years. The exclusion criteria were: (1) cardiac asthma, endometrial lesions of trachea, bronchogenic carcinoma, or allergic pulmonary infiltration; (2) hematological diseases, autoimmune disorders, or serious infections; (3) solid tumors or malignancies; and (4) pregnant or lactating women. And, 100 healthy controls in the physical examination center of Zibo hospital for the prevention and treatment of occupational diseases during the same period were included in this study. The healthy controls had normal lung function, and no history of asthma, autoimmune diseases, allergic diseases, blood diseases, severe infection, or malignant tumors.

Data and sample collection

Characteristics of all participants, including age, gender, and family history, were recorded. The laboratory examinations such as immune globulin E (IgE) and pulmonary ventilation function including forced expiratory volume in 1 s (FEV₁) and forced vital capacity (FVC) were recorded, followed by the calculation of FEV₁/FVC and FEV₁% predicted (FEV₁% pred). The exacerbation severity of BA-E patients were assessed based on the Global Strategy for Asthma Management and Prevention (updated 2010) on the day of hospital admission. Moreover, blood samples were collected using ethylenediaminetetraacetic acid tubes after confirming eligibility, followed by centrifugation at 1000 g for 15 min. The plasma was isolated and stored at −80°C for further examination.

Enzyme-linked immunosorbent assay (ELISA)

Levels of pro-inflammatory cytokines tumor necrosis factor-α (TNF-α), IL-6, and anti-inflammatory cytokine IL-10 in the serum were determined using ELISA kits (R&D Systems, Minneapolis, MN, USA) as per the instructions. The sample was incubated with coating solution at 37°C for 2 h in ELISA plates at 4°C overnight. Then, the sample was sealed with 10% bovine serum albumin (BSA) at 4°C overnight. After rinsing, the sample was incubated with primary antibodies at 37°C for 2 h and with secondary antibodies for 1 h. Termination solution was added after color reaction. Absorbance of each well at 450 nm was detected. The detailed information of ELISA kits were as follows: TNF-α (SRTA00, Range: 12.5-800 pg/mL, Sensitivity: 5 pg/mL), IL-6 (SR6000B, Range: 12.5-800 pg/mL, Sensitivity: 5 pg/mL).
Reverse transcription-quantitative polymerase chain reaction (RT-qPCR)

The total RNA was extracted using TRizol reagent (Invitrogen, Carlsbad, CA, USA) and transcribed into cDNA using PrimeScript RT reagent kit (Takara, Dalian, China). qPCR was conducted on ABI7900HT fast PCR real-time system (Applied Biosystems, Foster city, CA, USA) using SYBR® Premix Ex Taq™ II (Takara). Reaction conditions were as follows: pre-denaturation at 95°C for 10 min and 40 cycles of denaturation at 95°C for 10 s, annealing at 60°C for 20 s and extension at 72°C for 34 s. Data were analyzed using the 2^ΔΔCt method, with GAPDH and U6 as internal controls. Primers were synthesized by Shanghai Sangon Biotech Co., Ltd. (Shanghai, China). Primer sequences are illustrated in Table 1.

Bioinformatics analysis

The downstream target miRNAs of lncRNA PVT1 were predicted through ENCORI (http://starbase.sysu.edu.cn/agoClipRNA.php?source=lncRNA) and LncBase database (http://carolina.imis.athena-innovation.gr/diana_tools/web/index.php?r=lncbasev2%2Findex-predicted). Intersections were taken and screened to obtain the target miRNA.

Dual-luciferase reporter assay

The binding sites of lncRNA PVT1 and miR-423-5p were predicted through Starbase (http://starbase.sysu.edu.cn/agoClipRNA.php?source=lncRNA). The complementary sequences and mutant sequences of miR-423-5p and PVT1 were amplified and cloned onto pmiRGLO dual-luciferase reporter gene vectors (Promega, Madison, WI, USA). The wild-type plasmid PVT1-WT and mutant plasmid PVT1-MUT were constructed and transfected with mimetic NC or miR-423-5p mimic (GenePharma, Shanghai, China) into HEK293T cells (Shanghai Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences, Shanghai, China) using Lipofectamine™ 2000 (Invitrogen) as per the instructions. Luciferase activity was detected after 48 h of transfection.

Statistical analysis

SPSS 21.0 (IBM Corp., Armonk, NY, USA), GraphPad Prism 8 (GraphPad Software Inc., San Diego, CA, USA), and Medcalc® version 15.0 (Medcalc Software Ltd, Ostend, Belgium) statistical softwares were adopted for data analysis and graphing. Shapiro-Wilk test (W-test) was used to identify the normal distribution of data. Variable data were described as mean ± standard deviation or counts. Comparison between two groups was analyzed using the unpaired t-test or χ^2 test, while comparison among multiple groups was analyzed using one-way analysis of variance (ANOVA) and Tukey’s multiple comparisons test. The diagnostic value of lncRNA PVT1/miR-423-5p on BA was analyzed using receiver operating characteristic (ROC) curve. The differences of areas under the ROC curves were analyzed using MedCalc-Comparison of ROC curves. P < 0.05 was statistically significant.

Results

Comparative analysis of clinical data of BA patients and healthy controls

This study included 100 patients with BA-R, 100 patients with BA-E, and 100 healthy controls. The severity of BA-E patients was assessed and BA-E patients were further assigned into mild (31 cases), moderate (43 cases), and severe BA-E patients (26 cases). The clinical parameters of BA patients and healthy controls were compared and analyzed, and the result showed no significant difference in clinical baseline parameters (age, gender, and family history) and the data were comparable. The results of blood biochemical parameters showed that the IgE level was significantly increased in BA-R and BA-E patients, and the IgE level of BA-E patients was higher than that of BA-R patients. The examination of lung function parameters showed that FEV₁/FVC and FEV₁% pred were significantly reduced in BA-R and BA-E patients, and the values of BA-E patients was lower than that of BA-R patients. The values of inflammatory cytokine level showed that levels of TNF-α and IL-6 were decreased while IL-10 level was increased in BA-R and BA-E patients, and the differences between BA-R patients and BA-E patients were significant (all P < 0.001, Table 2).

Note: BA-R, bronchial asthma at remission; BA-E, bronchial asthma at exacerbation; FEV_1, forced expiratory volume in 1 s; FVC, forced vital capacity; P_a BA-R vs Control; P_b BA-E vs Control; P_c BA-E vs BA-R.

**LncRNA PVT1 was highly expressed in the serum of BA patients**

RT-qPCR showed that the expression of LncRNA PVT1 was significantly increased in the serum of BA-R and BA-E patients, and the PVT1 level of BA-E patients was higher than that of BA-R patients (Figure 1).

**miR-423-5p was poorly expressed in the serum of BA patients and negatively correlated with PVT1 expression**

One of the mechanisms of lncRNA in disease development could be explained by competitive endogenous RNA (ceRNA) theory. The effect of lncRNA/miRNA axis in BA has been reported previously, suggesting that it might be involved in the etiology of BA. To investigate the effect of LncRNA PVT1/miRNA axis in BA, 17 downstream miRNAs were obtained by screening through ENCORI and LncBase databases (Figure 2A). Among the 17 miRNAs, miR-423-5p has been reported to be downregulated in Th2-pretreated human airway epithelial cells, indicating a critical role in changing pro-inflammatory and anti-viral responses during BA-E. Meanwhile, the target relation of miR-141-3p and PVT1 was verified by dual-luciferase reporter assay (Figure 2B). RT-qPCR showed that miR-423-5p expression was significantly decreased in the serum of BA-R and BA-E patients, and miR-423-5p expression in the serum of BA-E patients was lower than that of BA-R patients (all P < 0.01, Figure 2C). In addition, Pearson’s correlation analysis showed that expression of LncRNA PVT1 was negatively correlated with miR-423-5p expression (P < 0.01, Figure 2D). Briefly, the LncRNA PVT1/miR-423-5p axis might be involved in of BA.

To further explore the value of LncRNA PVT1/miR-423-5p axis in BA diagnosis, the changes of LncRNA PVT1/miR-423-5p expressions in BA patients were analyzed. The
Role of lncRNA PVT1/miR-423-5p axis in BA

The expression of lncRNA PVT1/miR-423-5p was increased in the serum of BA-R and BA-E patients compared to controls. The diagnostic efficiency of lncRNA PVT1 and miR-423-5p in diagnosing BA-R patients was analyzed through ROC curve. The area under the ROC curve of lncRNA PVT1 diagnosing BA-R patients was 0.784 with sensitivity 0.60 and specificity 0.97; the area under the ROC curve of miR-423-5p diagnosing BA-R patients was 0.775 with sensitivity 0.78 and specificity 0.71; the area under the ROC curve of lncRNA PVT1/miR-423-5p diagnosing BA-R patients was 0.837 with sensitivity 0.74 and specificity 0.84. MedCalc-Comparison of ROC curves analysis showed that the areas under ROC curves among the three presented no significant difference (Figure 3B).

The above results indicated that the lncRNA PVT1/miR-423-5p axis had higher diagnostic efficiency in BA patients, especially in patients with BA-E.

Correlation analysis of lncRNA PVT1/miR-423-5p axis and clinical parameters

The correlation of lncRNA PVT1/miR-423-5p axis with biochemical parameters, pulmonary ventilation function, and inflammatory cytokines in BA-E and BA-R patients was analyzed. The result showed that the lncRNA PVT1/miR-423-5p axis in the serum of BA-R and BA-E patients was negatively correlated with FEV1/FVC, FEV1% pred, and IL-10, and positively correlated with IgE, TNF-α, and IL-6 (all P < 0.01, Table 3).

Correlation of lncRNA PVT1/miR-423-5p with BA severity in BA-E patients

Furthermore, changes of lncRNA PVT1/miR-423-5p in 31 mild BA-E patients, 43 moderate BA-E patients, and 16 severe BA-E patients were analyzed and the result showed that lncRNA PVT1 and the lncRNA PVT1/miR-423-5p axis were associated with increased severity while miR-423-5p was negatively correlated with BA severity (all P < 0.01, Figure 4A-C).

Discussion

BA is a common chronic disease of childhood with increasing prevalence at an alarming rate. Many lncRNAs and
miRNAs have been found to be potentially associated with asthma.20 This study demonstrated that LncRNA PVT1 was upregulated in the serum of BA patients while miR-423-5p was downregulated in the serum of BA patients and negatively associated with PVT1 expressions.

Generally, allergic BA is associated with the increase of serum IgE.21 In this study, the IgE level of BA-R and BA-E patients was remarkably increased and the IgE level of BA-E patients was comparatively higher than that of BA-R patients. BA severity is associated with FEV$_1$/FVC.22 Our study result showed that the value of FEV$_1$/FVC and FEV$_1$% pred were decreased in BA-R and BA-E patients. BA is characterized by elevated pro-inflammatory cytokines IL-6 and TNF-α.23 Changes of IL-10 expression are also associated with BA incidence and severity.24 Our result showed that levels of pro-inflammatory cytokines TNF-α and IL-6 were increased while anti-inflammatory cytokine IL-10 level was decreased in BA-R and BA-E patients, and the difference between BA-R and BA-E was significant. Based on a previous study, LncRNA PVT1 was clearly decreased in airway smooth muscle cells exposed to anti-asthma drugs.25 The expression level of LncRNA PVT1 was higher in the serum of children with asthma than in control children.26 In this study, expression of LncRNA PVT1 was significantly increased in the serum of BA-R and BA-E patients, and PVT1 level in BA-E patients was higher than that in BA-R patients, indicating that PVT1 expression pattern may be useful in BA diagnosis and helpful to distinguish BA-R from BA-E.

To further explore the effect of LncRNA PVT1 on BA, the downstream miRNAs of LncRNA PVT1 were investigated. miR-423-5p was found to be poorly expressed in the human airway smooth muscle cells pretreated with Th2.16 In our study, miR-423-5p expression was decreased in the serum of BA-R and BA-E patients, and miR-423-5p expression in the serum of BA-R patients was higher than that of BA-E patients. The target relation of PVT1 and miR-423-5p was verified by dual-luciferase reporter assay and expressions of LncRNA PVT1 and miR-423-5p were negatively correlated. The negative correlation of PVT1 and miR-423-5p was also found in thyroid cancer.27 Taken together, LncRNA PVT1/miR-423-5p axis might be involved in BA.

To investigate the diagnostic value of LncRNA PVT1/miR-423-5p on BA, changes of LncRNA PVT1/miR-423-5p expressions in BA patients were analyzed. In our study, expressions of LncRNA PVT1/miR-423-5p were increased in the serum of BA-R and BA-E patients, and expressions of LncRNA PVT1/miR-423-5p in BA-E patients were higher than that in BA-R patients. The area under the ROC curve

whether asthma patients had allergic asthma (whether antigen-specific IgE was positive) was not considered during enrollment. In future studies, we will further explore the clinical value of the lncRNA PVT1/miR-423-5p axis in patients with allergic and nonallergic asthma. Moreover, future studies will be carried out to explore the molecular regulatory mechanisms of lncRNA PVT1/miR-423-5p axis in BA.
