Abstract
Background: Airway remodeling is implicated in the pathogenesis of asthma, and abnormal proliferation of airway smooth muscle cells (ASMCs) contribute to airway remodeling. Inflammatory mediator, transforming growth factor-β1 (TGF-β1), stimulates the proliferation of ASMCs, and is associated with airway remodeling in asthma. Dexmedetomidine (DEX) has been widely used in the adjuvant therapy of acute asthma.

Objective: The potential effects of DEX on extracellular matrix (ECM) production and proliferation of ASMCs were investigated in this study.

Material and Methods: Human ASMCs were incubated with TGF-β1 for 48 hours, and then treated with different concentrations of DEX for another 24 hours. Cell proliferation was detected by MTT and BrdU (5′-bromo-2′-deoxyuridine) staining. Flow cytometry was used to assess cell apoptosis, and western blot was applied to identify the underlying mechanism.

Results: TGF-β1 induced increase in cell viability and bromodeoxyuridine (BrdU) positive cells in ASMCs while repressed cell apoptosis. Second, TGF-β1-induced ASMCs were then treated with different concentrations of DEX. Cell viability of TGF-β1-induced ASMCs was decreased by incubation of DEX. The number of BrdU positive cells in TGF-β1-induced ASMCs was reduced by incubation of DEX. Moreover, incubation of DEX promoted cell apoptosis of TGF-β1-induced ASMCs. Third, incubation of DEX attenuated TGF-β1-induced increase in fibronectin, collagen I, MMP9, and versican in ASMCs. Lastly, the up-regulation of phosphorylated extracellular receptor kinase (p-ERK), phosphorylated Jun N-terminal Kinase (p-JNK), and p-p38 in TGF-β1-induced ASMCs was reversed by incubation of DEX.

Conclusion: DEX suppressed TGF-β1-induced ECM production and proliferation of ASMCs through inactivation of p38 mitogen-activated protein kinase (MAPK) pathway, providing a potential strategy for prevention of asthma.

Introduction

Asthma is one of the most common chronic diseases, and its prevalence has increased in the past few years. Asthma is characterized by airway remodeling, inflammation, and hyperresponsiveness. Airway remodeling with structural changes in the airway wall, including airway smooth muscle cells (ASMCs) hyperplasia, extracellular matrix (ECM) production, and basement membrane thickening, is the primary clinical manifestation of asthma. Increased proliferation of ASMCs results in obstruction and narrowing of airway, promotes accumulation of ECM and ultimately contributes to airway remodeling. Therefore, ASMCs are considered as therapeutic target of asthma.

Previous study demonstrated that transforming growth factor-β1 (TGF-β1) was elevated in the airway submucosa of asthmatic patients, especially the submucosal eosinophils. Eosinophil recruitment was impaired in allergic asthma (importance of basophils in eosinophilic asthma: the murine counterpart). Accumulation of TGF-β1 in the activated eosinophils contributed to the development of airway fibrosis in chronic asthma. TGF-β1 also suppressed cytokine secretion of group 2 innate lymphoid cells, and participated in cellular contact between regulatory T cells and lymphoid cells during allergic asthma and respiratory disease. TGF-β1 functions as a modulator of fibrotic response, and promotes the protein expression involved in ECM deposition. In addition, TGF-β1 also increases the proliferation of ASMCs, thus driving airway remodeling. Inhibition of TGF-β1-induced ECM deposition and proliferation in ASMCs is beneficial to airway remodeling.

Dexmedetomidine (DEX) is an α2-adrenoceptor agonist that exerts sedative and analgesic effects, and has been widely used in clinical anesthesia. Moreover, dexmedetomidine also demonstrates protective effect on various organs. For example, dexmedetomidine ameliorated ischemia-reperfusion-induced renal or myocardial injury through suppression of inflammatory response. Dexmedetomidine also protected against oxygen-glucose deprivation-induced cell apoptosis in cardiomyocytes or autophagy in astrocytes. Lipopolysaccharide-induced neuronal apoptosis was repressed by dexmedetomidine. Dexmedetomidine was also used in chronic obstructive pulmonary disease. For example, dexmedetomidine inhibited the cell apoptosis of cigarette smoke extract-induced bronchial and alveolar epithelial cells, and suppressed inflammation and oxidative stress to attenuate cell injury.

Clinically, dexmedetomidine was used as adjuvant therapy in anxiety and agitation or acute respiratory failure in asthmatic patients. However, the mechanism of dexmedetomidine in asthma has not been reported yet.

In this study, ASMCs were incubated with TGF-β1 according to the method described in previous study, and the effects of dexmedetomidine were investigated on ECM production and proliferation.

Materials and Methods

Cell culture and treatment

Human ASMCs (American Type Culture Collection, Manassas, VA, USA) were cultured in Dulbecco’s Modified Eagle’s Medium (DMEM; Gibco, Rockville, MD, USA) containing penicillin-streptomycin (Sigma-Aldrich, St. Louis, MO, USA) and 10% fetal bovine serum (Gibco). ASMCs were plated and incubated with 10-ng/mL TGF-β1 (Sigma-Aldrich) for 48 h, and treated with different concentrations of dexmedetomidine (0.25, 0.5, and 1 nM) (Sigma-Aldrich) for another 24 h.

Cell viability, proliferation and apoptosis assays

TGF-β1-induced ASMCs post-dexmedetomidine condition was seeded in 96-well plate for 72 h, and incubated with MITT solution (Invitrogen, Carlsbad, CA, USA) for 4 h. Absorbance at 570 nm was measured via microplate reader (Thermo Fisher Scientific, Waltham, MA, USA). For incorporation of bromodeoxyuridine (BrdU) positive cells, TGF-β1-induced ASMCs, post dexmedetomidine condition, were incubated with 10-μM BrdU (Sigma-Aldrich) for 3 h. Cold ethanol/HCl-fixed cells were permeabilized in 0.25% Triton X-100, blocked with 1% bovine serum albumin (BSA), and incubated with anti-BrdU antibody and Alexa Fluor 594-conjugated secondary antibody from BrdU labeling and detection kit III (Roche Diagnostics GmbH, Mannheim, Germany). The nuclei were counterstained with DAPI. Cells were analyzed with cytometer (CompuCyte, Cambridge, MA, USA). For flow cytometry, TGF-β1-induced ASMCs post-dexmedetomidine condition were harvested, and resuspended in binding buffer from Annexin V-FITC/PI Apoptosis Detection Kit (Becton Dickinson Biosciences, San Jose, CA, USA). Cells were stained with propidium iodide (PI) and annexin V-FITC, and analyzed with FACScalibur™ flow cytometer (Becton Dickinson Biosciences).

Western blot test

Protein samples were isolated from ASMCs cells using RIPA lysis buffer (Beyotime, Beijing, China). Samples were separated by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), and transferred onto nitrocellulose membranes. The membranes were blocked with skimmed milk and probed with specific antibodies: anti-Bax (ab216494) and anti-Bcl-2 (ab59348) (1:2000; Abcam, Cambridge, UK); anti-cleaved caspase-3 (ab2302) and anti-cleaved caspase-9 (ab2324) (1:2500, Abcam); anti-fibronectin (ab2413) and anti-collagen I (ab34710) (1:3000, Abcam); anti-MMP9 (ab38898) and anti-versican (ab19345) (1:3500, Abcam); anti-extracellular receptor kinase (ERK) (ab17942) and anti-phosphorylated (p)-ERK (ab278538) (1:4000, Abcam); and anti-Jun N-terminal kinase (JNK) (ab179461), anti-p-JNK (ab4821), anti-p38 (ab170099), anti-p-p38 (ab4822), and anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (ab9485) (1:4500, Abcam). Following incubation with horseradish peroxidase-conjugated secondary antibody from Becton Dickinson Biosciences, the protein bands were visualized using chemiluminescence (Sigma-Aldrich). The Quantity One software (Bio-Rad Laboratories Inc., Hercules, CA, USA) was used to quantify the protein bands with GAPDH as a reference.
**Statistical analysis**

All the data with at least triple replicates were expressed as mean ± standard error of mean (SEM) and analyzed by Student’s t-test or one-way analysis of variance (ANOVA) with the SPSS software. P < 0.05 was considered as statistically significant.

**Results**

**Dexmedetomidine suppressed cell proliferation of TGF-β1-induced ASMCs**

In order to establish asthmatic cell model, ASMCs were treated with TGF-β1. TGF-β1 significantly increased the cell viability of ASMCs (P < 0.01; Figure 1A), and promoted cell proliferation (P < 0.01; Figure 1B) through up-regulation of BrdU positive cells (Figure 1C). Dexmedetomidine incubation reduced cell viability of TGF-β1-induced ASMCs in a dosage-dependent manner (Figure 1A), and repressed cell proliferation (Figures 1B and 1C). Therefore, dexmedetomidine decreased proliferation of TGF-β1-induced ASMCs.

**Dexmedetomidine promoted cell apoptosis of TGF-β1-induced ASMCs**

Cell apoptosis of ASMCs was significantly repressed by TGF-β1 condition (P < 0.01; Figure 2A), while dexmedetomidine promoted the apoptosis of TGF-β1-induced ASMCs in a dosage-dependent manner (Figure 2A). TGF-β1-induced increase in Bcl-2 expression and decrease in Bax-cleaved caspase-3 and cleaved caspase-9 expression in ASMCs were reversed by incubation of dexmedetomidine (Figure 2B), suggesting the pro-apoptotic role of dexmedetomidine in TGF-β1-induced ASMCs.

**Dexmedetomidine repressed extracellular matrix production of TGF-β1-induced ASMCs**

Protein expression levels of fibronectin, collagen I, MMP9, and versican were significantly up-regulated in ASMCs post-TGF-β1 condition (P < 0.01; Figure 3). However, incubation of dexmedetomidine reduced expression of fibronectin, collagen I, MMP9, and versican in TGF-β1-induced ASMCs in a dosage-dependent manner (Figure 3), demonstrating that dexmedetomidine protected ASMCs against TGF-β1-induced ECM deposition.

Dexmedetomidine incubation reduced expression of fibronectin, collagen I, MMP9, and versican normalized to GAPDH in TGF-β1-induced ASMCs. N = 3. Dunnett’s test was performed for statistical analysis. *vs. control, P < 0.01. # vs. 0-nM dexmedetomidine (DEX), P < 0.05, P < 0.01.

Dexmedetomidine repressed activation of mitogen-activated protein kinase (MAPK) signaling in TGF-β1-induced ASMCs

Although protein expression levels of JNK, ERK, and p38 were not affected by TGF-β1 condition (Figure 4), p-JNK, p-ERK, and p-p38 were significantly up-regulated in TGF-β1-induced ASMCs (P < 0.01; Figure 4). Moreover, incubation of dexmedetomidine decreased expression of p-JNK, p-ERK, and p-p38 in TGF-β1-induced ASMCs in a dosage-dependent manner (Figure 4), indicating the suppressive effect of dexmedetomidine on MAPK signaling in TGF-β1-induced ASMCs.
in ASMCs, thus promoting ECM deposition. Previous study has demonstrated the pro-apoptotic effect of dexmedetomidine on esophageal cancer cells.20 The components of ECM, including Tenascin C, matrix metalloproteinase 16, collagen IV, and fibronectin, were reduced in breast cancer cells by dexmedetomidine condition.21 Results in this study established that dexmedetomidine incubation suppressed cell proliferation of TGF-β1-induced ASMCs, promoted cell apoptosis, and reduced ECM deposition by down-regulating fibronectin, collagen I, MMP9, and versican. These results indicated that dexmedetomidine protected ASMCs against TGF-β1-induced ECM deposition and proliferation, thus alleviating airway remodeling in the development of asthma. However, TGF-β1 also contributes to airway remodeling through induction of ASMCs migration,31 and dexmedetomidine suppressed the cell migration of esophageal cancer.29 The effect of dexmedetomidine on the migration of TGF-β1-induced ASMCs must be investigated in the future research.

Mitogen-activated protein kinase signaling cascades are responsible for migration, degranulation, proliferation, activation, and differentiation of ASMCs and immune cells, and modulate airway remodeling in the development of asthma.32 MAPKs are regarded as potential targets for the treatment of asthma.33 TGF-β1 has been demonstrated to induce activation of MAPK in ASMCs, thereby promoting the proliferation, migration, and ECM deposition of ASMCs.34 Inhibition of MAPK prevented airway remodeling.35 Studies have proved that dexmedetomidine inhibited activation of MAPK signaling to protect against lidocaine-induced cytotoxicity,36 isoflurane-induced neuroapoptosis,37 and repressed ovarian cancer growth.38 Here, dexmedetomidine attenuated TGF-β1-induced increase in p-JNK, p-ERK, and p-p38 in ASMCs, thus inhibiting the activation of MAPKs.

Conclusion

The current study indicated that dexmedetomidine retarded airway remodeling in asthma through suppression of ECM deposition and proliferation in TGF-β1-induced
ASMCs. Inactivation of MAPK signaling was involved in dexmedetomidine-suppressed airway remodeling. Therefore, dexmedetomidine has the potential to be used clinically for the prevention of asthma. However, there are limitations to the current study. The effects of dexmedetomidine on ASMCs migration must be studied and the ovalbum-induced asthmatic animal model must be established in the future studies to investigate in vivo effects of dexmedetomidine on asthma.
